Bottom-Up Parsing

What is Bottom-Up Parsing?

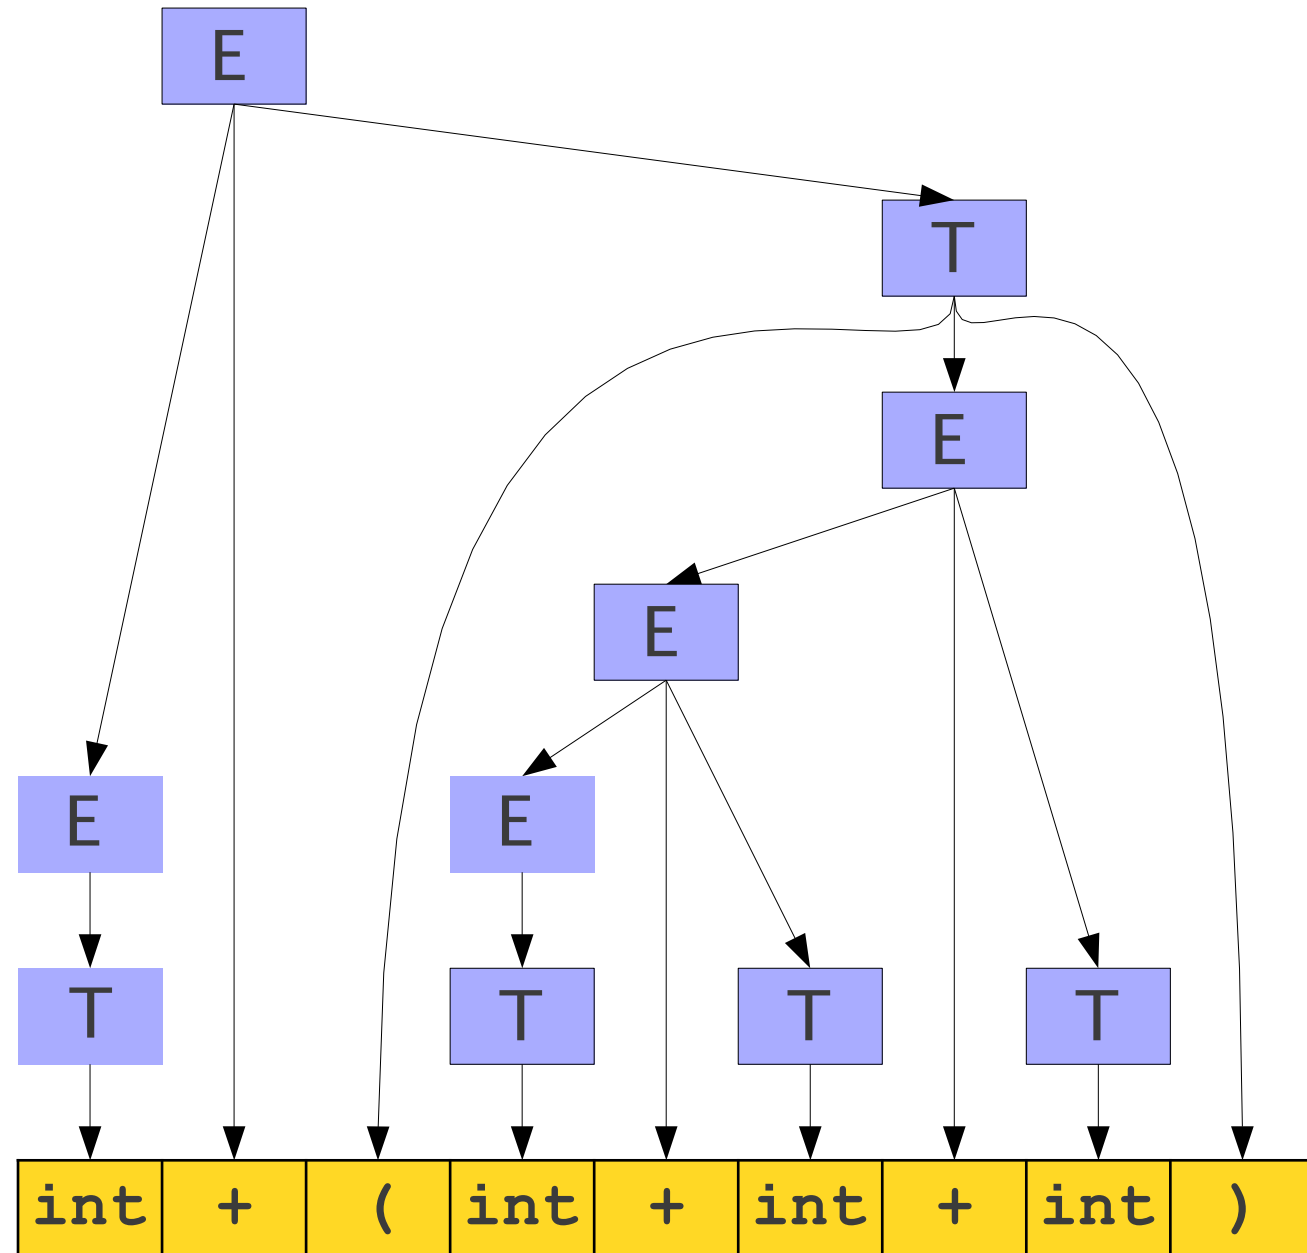

- Idea: Apply productions **in reverse** to convert the user's program to the start symbol.
 - We can think of bottom-up parsing as the process of "reducing" a string w to the start symbol of the grammar. At each reduction step, a specific substring matching the body of a production is replaced by the nonterminal at the head of that production.
- Terms
 - Reductions, handle, shift-reduce parsing, conflicts, LR grammars

What is Bottom-Up Parsing?

- We'll be exploring four **directional**, **predictive** bottom-up parsing techniques:
 - **Directional**: Scan the input from left-to-right.
 - **Predictive**: Guess which production should be inverted.
 - The largest class of grammars for which shift-reduce parsers can be built, the LR grammars:
LR(1), LALR(1)

One View of a Bottom-Up Parse

$E \rightarrow T$
 $E \rightarrow E + T$
 $T \rightarrow \text{int}$
 $T \rightarrow (E)$

A Second View of a Bottom-Up Parse

$E \rightarrow T$	$\text{int} + (\text{int} + \text{int} + \text{int})$
$E \rightarrow E + T$	$\Rightarrow T + (\text{int} + \text{int} + \text{int})$
$T \rightarrow \text{int}$	$\Rightarrow E + (\text{int} + \text{int} + \text{int})$
$T \rightarrow (E)$	$\Rightarrow E + (T + \text{int} + \text{int})$
	$\Rightarrow E + (E + \text{int} + \text{int})$
	$\Rightarrow E + (E + T + \text{int})$
	$\Rightarrow E + (E + \text{int})$
	$\Rightarrow E + (E + T)$
	$\Rightarrow E + (E)$
	$\Rightarrow E + T$
	$\Rightarrow E$

A Second View of a Bottom-Up Parse

$E \rightarrow T$	$\text{int} + (\text{int} + \text{int} + \text{int})$
$E \rightarrow E + T$	$\Rightarrow T + (\text{int} + \text{int} + \text{int})$
$T \rightarrow \text{int}$	$\Rightarrow E + (\text{int} + \text{int} + \text{int})$
$T \rightarrow (E)$	$\Rightarrow E + (T + \text{int} + \text{int})$
	$\Rightarrow E + (E + \text{int} + \text{int})$
	$\Rightarrow E + (E + T + \text{int})$
	$\Rightarrow E + (E + \text{int})$
	$\Rightarrow E + (E + T)$
	$\Rightarrow E + (E)$
	$\Rightarrow E + T$
	$\Rightarrow E$

A left-to-right, bottom-up parse is a rightmost derivation traced in reverse.

A Third View of a Bottom-Up Parse

`int + (int + int + int)`
⇒ `T + (int + int + int)`
⇒ `E + (int + int + int)`
⇒ `E + (T + int + int)`
⇒ `E + (E + int + int)`
⇒ `E + (E + T + int)`
⇒ `E + (E + int)`
⇒ `E + (E + T)`
⇒ `E + (E)`
⇒ `E + T`
⇒ `E`

Each step in this bottom-up parse is called a **reduction**. We **reduce** a substring of the sentential form back to a nonterminal

Handles

- The **handle** of a parse tree T is the leftmost complete cluster of leaf nodes.
- A left-to-right, bottom-up parse works by iteratively searching for a handle, then reducing the handle.

Handles

- Informally, a **handle of a string is a substring that matches the right side of a production rule.**

But not every substring matches the right side of a production rule is handle

- A **handle** of a right sentential form $\gamma (\equiv \alpha\beta\omega)$ is a production rule $A \rightarrow \beta$ and a position of γ where the string β may be found and replaced by A to produce the previous right-sentential form in a rightmost derivation of γ .

$$\begin{array}{c} * \\ S \xRightarrow{rm} \alpha \mathbf{A} \omega \xRightarrow{rm} \alpha \mathbf{\beta} \omega \end{array}$$

- If the grammar is unambiguous, then every right-sentential form of the grammar has exactly one handle.

Handle Pruning

A right-most derivation in reverse can be obtained by **handle-pruning**.

$$S = \gamma_0 \underset{\text{rm}}{\Rightarrow} \gamma_1 \underset{\text{rm}}{\Rightarrow} \gamma_2 \underset{\text{rm}}{\Rightarrow} \dots \underset{\text{rm}}{\Rightarrow} \gamma_{n-1} \underset{\text{rm}}{\Rightarrow} \gamma_n = \omega$$

← input string

Start from γ_n , find a handle $A_n \rightarrow \beta_n$ in γ_n ,
and replace β_n in by A_n to get γ_{n-1} .

Then find a handle $A_{n-1} \rightarrow \beta_{n-1}$ in γ_{n-1} ,
and replace β_{n-1} in by A_{n-1} to get γ_{n-2} .

Repeat this, until we reach S.

A Shift-Reduce Parser

$E \rightarrow E+T \mid T$

$T \rightarrow T^*F \mid F$

$F \rightarrow (E) \mid id$

Right-Most Derivation of $id+id*id$

$E \Rightarrow E+T \Rightarrow E+T^*F \Rightarrow E+T^*id \Rightarrow E+F^*id$

$\Rightarrow E+id^*id \Rightarrow T+id^*id \Rightarrow F+id^*id \Rightarrow id+id^*id$

Right-Most Sentential Form

id+id*id

F+id*id

T+id*id

E+id*id

E+F*id

E+T*id

E+T*F

E+T

E

Reducing Production

$F \rightarrow id$

$T \rightarrow F$

$E \rightarrow T$

$F \rightarrow id$

$T \rightarrow F$

$F \rightarrow id$

$T \rightarrow T^*F$

$E \rightarrow E+T$

Handles are red and underlined in the right-sentential forms.

A Stack Implementation of A Shift-Reduce Parser

There are four possible actions of a shift-parser action:

- **Shift** : The next input symbol is shifted onto the top of the stack.
- **Reduce**: Replace the handle on the top of the stack by the non-terminal.
- **Accept**: Successful completion of parsing.
- **Error**: Parser discovers a syntax error, and calls an error recovery routine.

Initial stack just contains only the end-marker \$.

The end of the input string is marked by the end-marker \$.

A Stack Implementation of A Shift-Reduce Parser

<u>Stack</u>	<u>Input</u>	<u>Action</u>
\$	id+id*id\$	shift
\$id	+id*id\$	reduce by $F \rightarrow id$
\$F	+id*id\$	reduce by $T \rightarrow F$
\$T	+id*id\$	reduce by $E \rightarrow T$
\$E	+id*id\$	shift
\$E+	id*id\$	shift
\$E+id	*id\$	reduce by $F \rightarrow id$
\$E+F	*id\$	reduce by $T \rightarrow F$
\$E+T	*id\$	shift
\$E+T*	id\$	shift
\$E+T*id	\$	reduce by $F \rightarrow id$
\$E+T*F	\$	reduce by $T \rightarrow T*F$
\$E+T	\$	reduce by $E \rightarrow E+T$
\$E	\$	accept

Parse Tree

Summarizing Our Intuition

- Our first intuition (reconstructing the parse tree bottom–up) motivates how the parsing should work.
- Our second intuition (rightmost derivation in reverse) describes the order in which we should build the parse tree.
- Our third intuition (handle pruning) is the basis for the bottom–up parsing algorithms we will explore.

This reduction
wasn't a handle!

The leftmost reduction
isn't always the handle.

Finding Handles

- Where do we look for handles?
 - Where in the string might the handle be?
- How do we search for possible handles?
 - Once we know where to search, how do we identify candidate handles?
- How do we recognize handles?
 - Once we've found a candidate handle, how do we check that it really is the handle?

Question One:

Where are handles?

Where are Handles?

- Recall: A left-to-right, bottom-up parse traces a rightmost derivation in reverse.
- Each time we do a reduction, we are reversing a production applied to the *rightmost* nonterminal symbol.
- Suppose that our current sentential form is $\alpha\gamma\omega$, where γ is the handle and $A \rightarrow \gamma$ is a production rule.
- After reducing γ back to A , we have the string $\alpha A\omega$. Thus ω must consist purely of terminals, since otherwise the reduction we just did was not for the rightmost terminal.

Why This Matters

- Suppose we want to parse the string γ .
We will break γ into two parts, α and ω ,
- where
 - α consists of both terminals and nonterminals,
and
 - ω consists purely of terminals.
- Our search for handles will concentrate purely in α .
- As necessary, we will start moving terminals from ω over into α .

Shift/Reduce Parsing

- The bottom-up parsers we will consider are called **shift/reduce** parsers.

Contrast with the LL(1) **predict/match** parser.

- Idea: Split the input into two parts:
 - Left substring is our work area; all handles must be here.
 - Right substring is input we have not yet processed; consists purely of terminals.
- At each point, decide whether
 - to: Move a terminal across the split (shift)
 - Reduce a handle (reduce)

E

An Important Observation

- All of the reductions we applied were to the far right end of the left area.
- This is not a coincidence; all reductions are always applied all the way to the end of the left area.
- Inductive proof sketch:
 - After no reduces, the first reduction can be done at the right end of the left area.
 - After at least one reduce, the very right of the left area is a nonterminal. This nonterminal must be part of the next reduction, since we're tracing a rightmost derivation backwards.

An Important Corollary

- Since reductions are always at the right side of the left area, we never need to shift from the left to the right.
- No need to “uncover” something to do a reduction.
- Consequently, shift/reduce parsing means
 - **Shift**: Move a terminal from the right to the left area.
 - **Reduce**: Replace some number of symbols at the right side of the left area.

Simplifying our Terminology

- All activity in a shift/reduce parser is at the far right end of the left area.
- Idea: Represent the left area as a stack.
Shift: Push the next terminal onto the
• stack.
- Reduce: Pop some number of symbols from the stack, then push the appropriate nonterminal.

Finding Handles

- Where do we look for handles?

At the top of the stack.

- How do we search for handles?

What algorithm do we use to try to discover a handle?

- How do we recognize handles?

Once we've found a possible handle, how do we confirm that it's correct?

Question Two:

How do we search for handles?

Searching for Handles

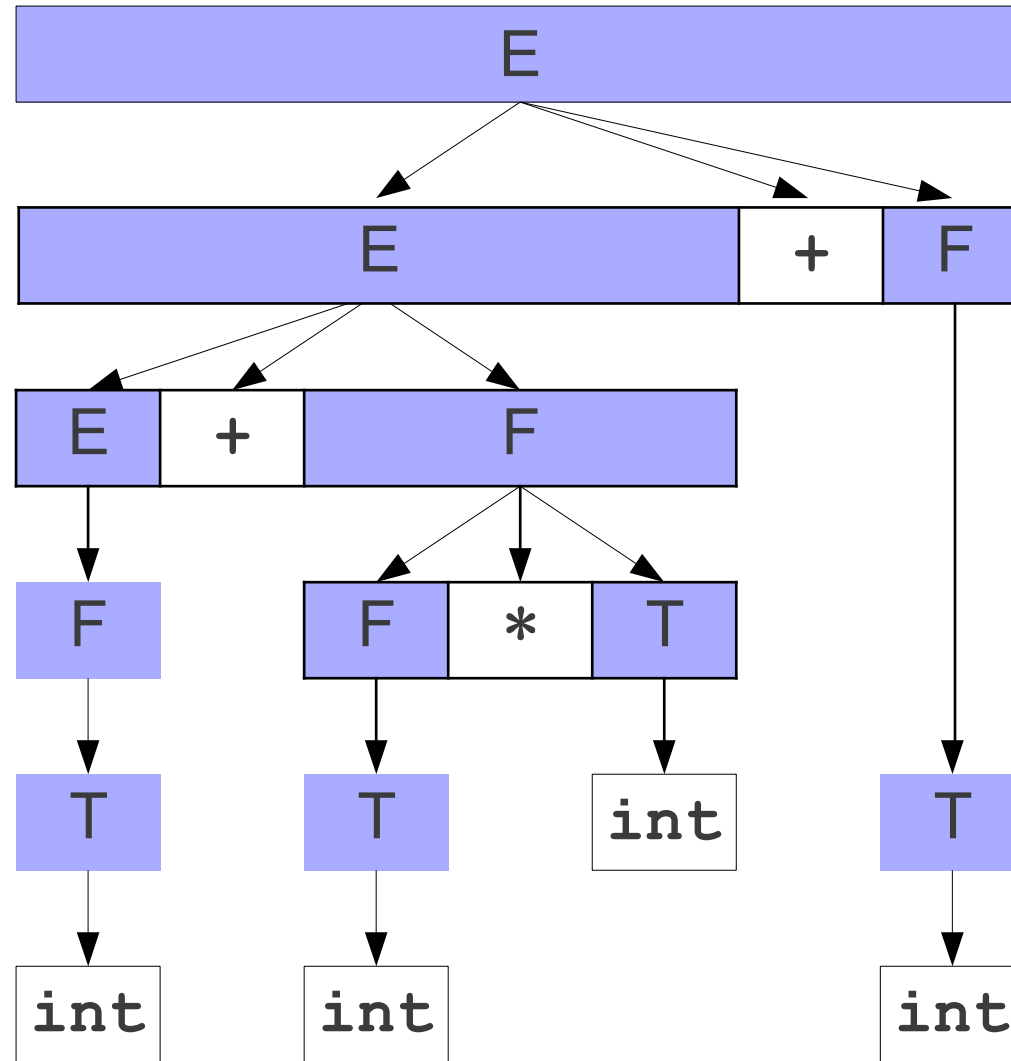

- When using a shift/reduce parser, we must decide whether to shift or reduce at each point.
- We only want to reduce when we know we have a handle.
- **Question:** How can we tell that we might be looking at a handle?

Exploring the Left Side

- The handle will always appear at the end of string in the left side of the parser.
- Can *any* string appear on the left side of the parser, or are there restrictions on what sorts of strings can appear there?
- If we can find a pattern to the strings that can appear on the left side, we might be able to exploit it to detect handles.

A diagram showing a stack structure. It consists of a light blue horizontal rectangle with a thin black border. Inside the rectangle, the letter 'E' is centered. To the right of the rectangle is a vertical red line, acting as a cursor or pointer to the top of the stack.

E

An Important Result

- There are only finitely many productions, and within those productions only finitely many positions.
- At any point in time, we only need to track where we are in one production.
- There are only finitely many options we can take at any one point.
- **We can use a finite automaton as our recognizer.**

An Automaton for Left Areas

Constructing the Automaton

- Create a state for each nonterminal.
- For each production $\mathbf{A} \rightarrow \gamma$
 - Construct states $\mathbf{A} \rightarrow \alpha \cdot \omega$ for each possible way of splitting γ into two substrings α and ω .
 - Add transitions on x between $\mathbf{A} \rightarrow \alpha \cdot x \omega$ and $\mathbf{A} \rightarrow \alpha x \cdot \omega$.
- For each state $\mathbf{A} \rightarrow \alpha \cdot \mathbf{B} \omega$ for nonterminal \mathbf{B} , add an ε -transition from $\mathbf{A} \rightarrow \alpha \cdot \mathbf{B} \omega$ to \mathbf{B} .

Why This Matters

- Our initial goal was to find handles.
- When running this automaton, if we ever end up in a state with a rule of the form

$$\mathbf{A} \rightarrow \omega \cdot$$

- Then we might be looking at a handle.
- This automaton can be used to discover possible handle locations!

Adding Determinism

- Typically, this handle-finding automaton is implemented deterministically.
- We could construct a deterministic parsing automaton by constructing the nondeterministic automaton and applying the subset construction, but there is a more direct approach.

A Deterministic Automaton

$S \rightarrow E$
 $E \rightarrow T;$
 $E \rightarrow T + E$
 $T \rightarrow \text{int}$
 $T \rightarrow (E)$

 $T \rightarrow (E)$

A Deterministic Automaton

$S \rightarrow E$
 $E \rightarrow T;$
 $E \rightarrow T + E$
 $T \rightarrow \text{int}$
 $T \rightarrow (E)$

Constructing the Automaton II

- Begin in a state containing $S \rightarrow \cdot A$, where S is the augmented start symbol.
- Compute the **closure** of the state:
 - If $A \rightarrow \alpha \cdot B\omega$ is in the state, add $B \rightarrow \cdot \gamma$ to the state for each production $B \rightarrow \gamma$.
 - Yet another fixed-point iteration!
- Repeat until no new states are added:
 - If a state contains a production $A \rightarrow \alpha \cdot x\omega$ for symbol x , add a transition on x from that state to the state containing the closure of $A \rightarrow \alpha x \cdot \omega$
- This is equivalent to a subset construction on the NFA.

Handle-Finding Automata

- Handling-finding automata can be very large.
- NFA has states proportional to the size of the grammar, so DFA can have size exponential in the size of the grammar.
 - There are grammars that can exhibit this worst-case.
 - Automata are almost always generated by tools like **bison**.

Finding Handles

- Where do we look for handles?
 - **At the top of the stack.**
- How do we search for possible handles?
 - **Build a handle-finding automaton.**
- How do we recognize handles?
 - Once we've found a candidate handle, how do we check that it really is the handle?

Question Two:

How do we recognize handles?

Handle Recognition

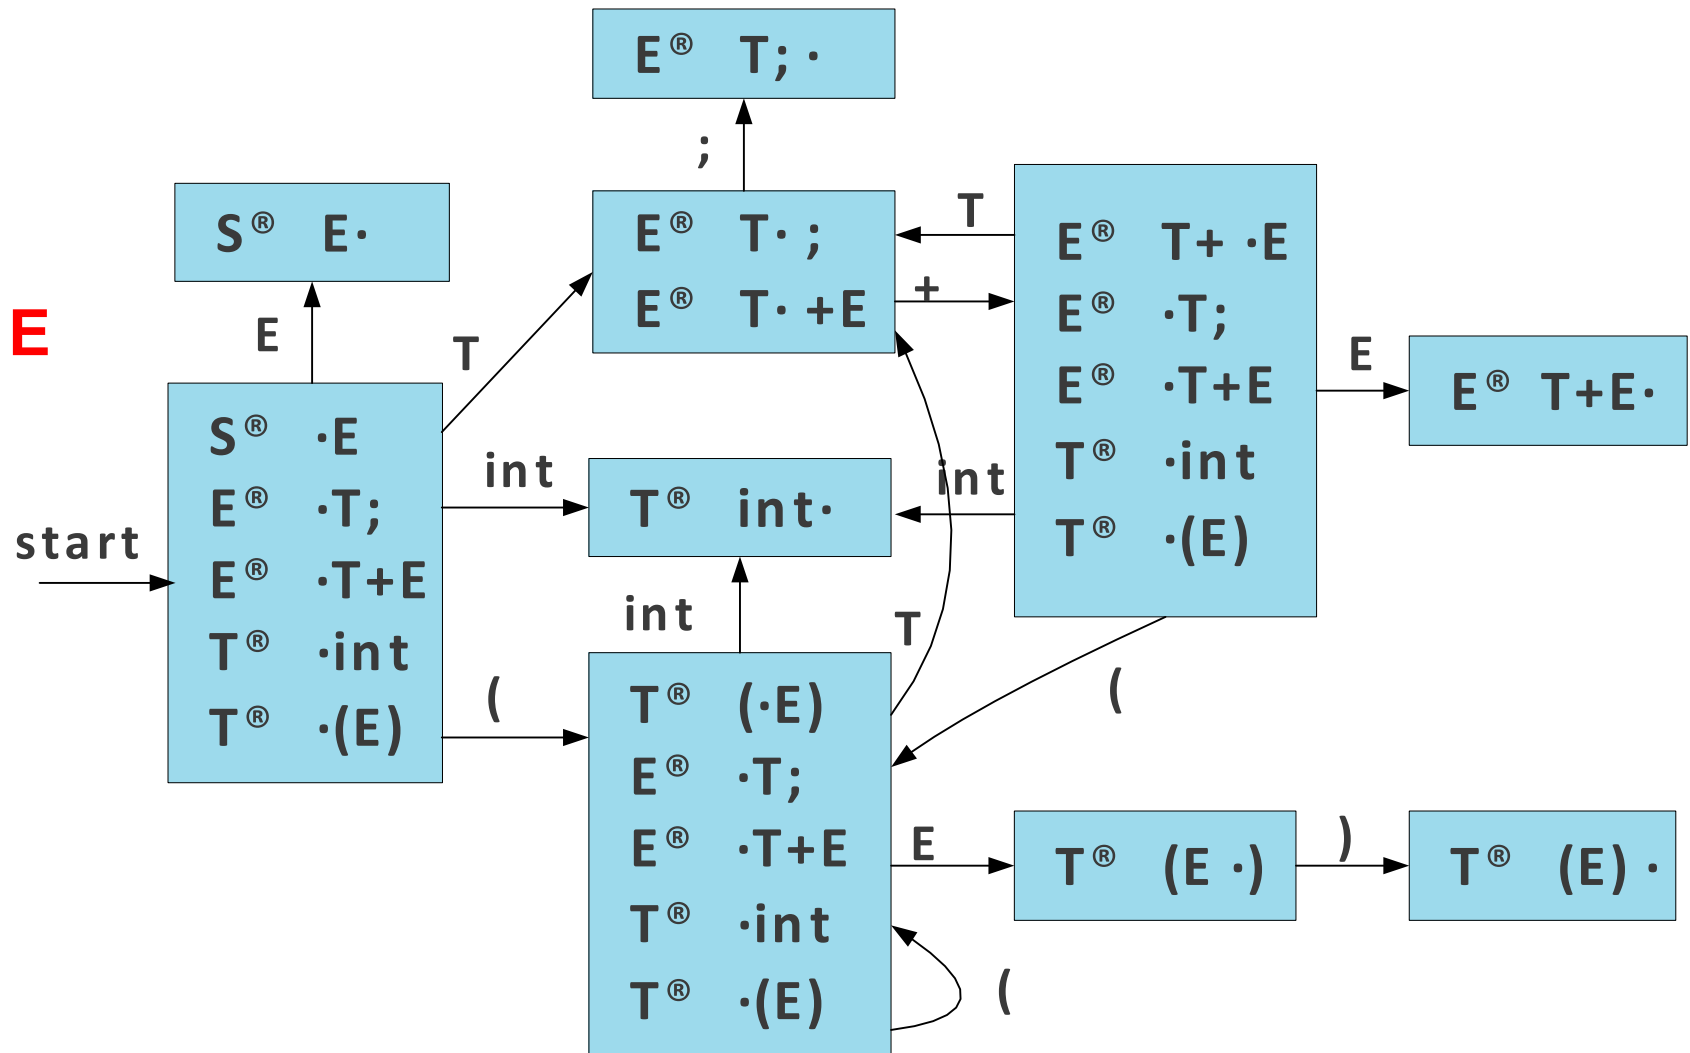

- Our automaton will tell us all places where a handle might be.
- However, if the automaton says that there might be a handle at a given point, we need a way to confirm this.
- We'll thus use **predictive bottom-up parsing**:
 - Have a deterministic procedure for guessing where handles are.
- There are many predictive algorithms, each of which recognize different grammars.

The First Algorithm: LR(0)

- Bottom-up predictive parsing with:
 - **L**: Left-to-right scan of the input.
 - **R**: Rightmost derivation.
 - (**0**): Zero tokens of lookahead.
- Use the handle-finding automaton, without any lookahead, to predict where handles are.

5	9			8		2	3		Shift
6									Reduce T → (E)
7					6				Shift
8	9			8		7	3		Shift
9									Reduce T → int

LR Tables

[illegible]

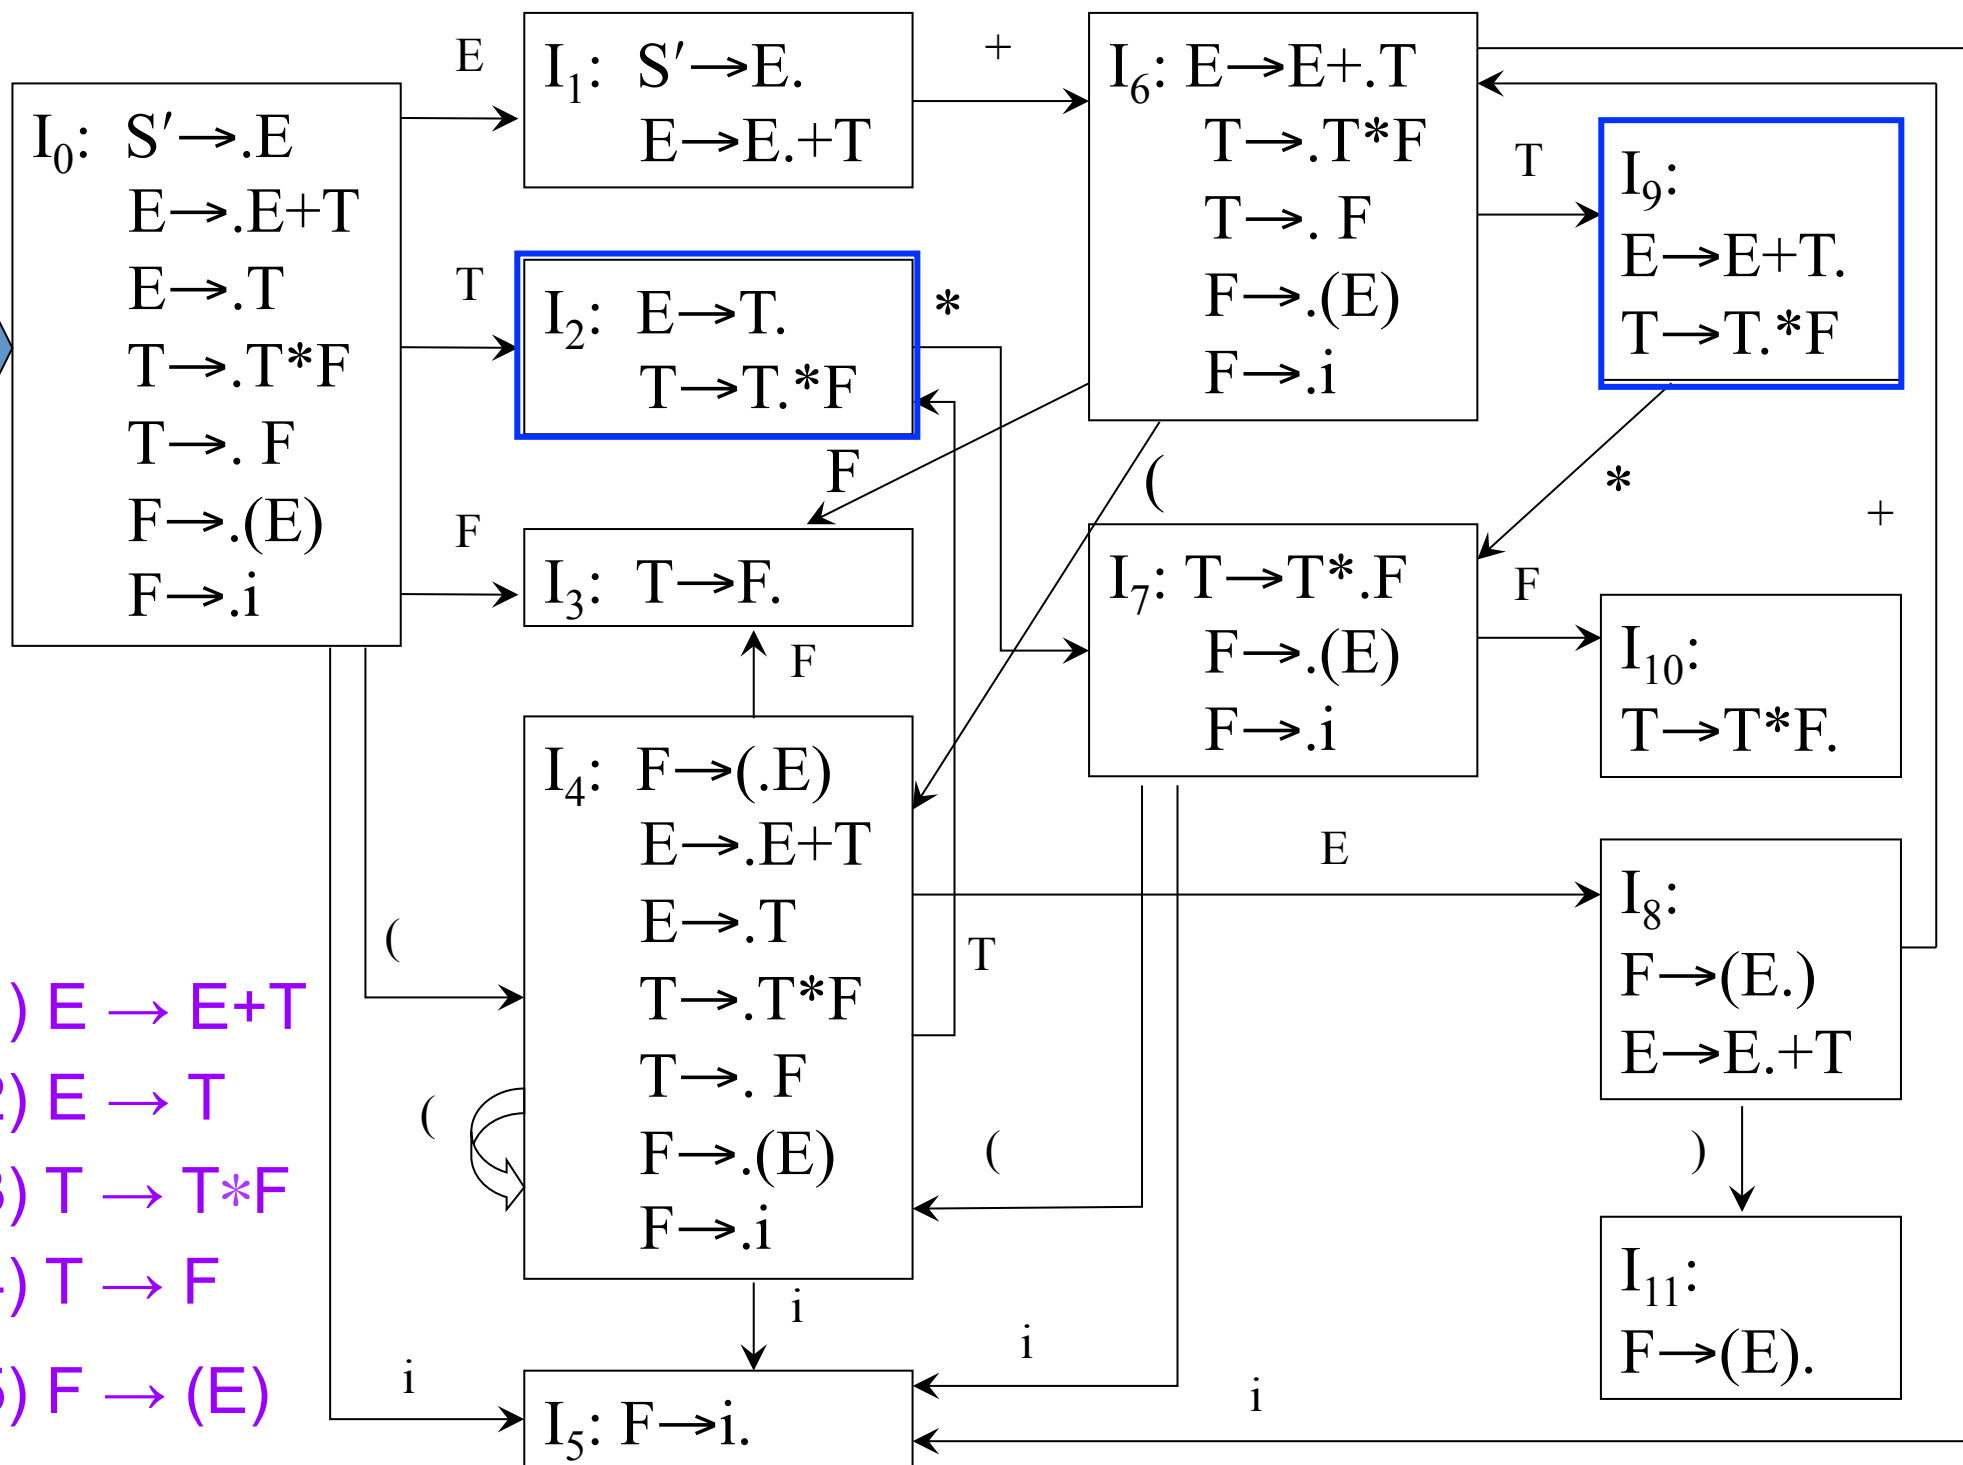

Representing the Automaton

- The ACTION function takes as arguments a state i and a terminal a (or $\$$, the input endmarker). The value of $ACTION[i, a]$ can have one of four forms:
 - a) **Shift j** , where j is a state. The action taken by the parser effectively shifts input a to the stack, but uses state j to represent a .
 - b) **Reduce $A \rightarrow \beta$** . The action of the parser effectively reduces β on the top of the stack to head A .
 - c) **Accept**. The parser accepts the input and finishes parsing;
 - d) **Error**.
- We extend the GOTO function, defined on sets of items, to states: if $GOTO[I_i, A] = I_j$, then GOTO also maps a state i and a nonterminal A to state j .

The Limits of LR(0)

- (1) $E \rightarrow E+T$
- (2) $E \rightarrow T$
- (3) $T \rightarrow T*F$
- (4) $T \rightarrow F$
- (5) $F \rightarrow (E)$
- (6) $F \rightarrow i$

LR(0) table for the expression grammar

state	ACTION					
	i	+	*	()	\$
2	r2	r2	r2/s7	r2	r2	r2
3	r4	r4	r4	r4	r4	r4
					
9	r1	r1	r1/s7	r1	r1	r1
10	r3	r3	r3	r3	r3	r3
11	r5	r5	r5	r5	r5	r5

LR Conflicts

A **shift/reduce conflict** is an error where a shift/reduce parser cannot tell whether to shift a token or perform a reduction.

A **reduce/reduce conflict** is an error where a shift/reduce parser cannot tell which of many reductions to perform.

A grammar whose handle-finding automaton contains a shift/reduce conflict or a reduce/reduce conflict is not LR(0).

(1) $E \rightarrow E+T$

(2) $E \rightarrow T$

(3) $T \rightarrow T * F$

(4) $T \rightarrow F$

(5) $F \rightarrow (E)$

Conflicts During Shift-Reduce Parsing

- There are context-free grammars for which shift-reduce parsers cannot be used.
- Stack contents and the next input symbol may not decide action:
 - shift/reduce conflict**: Whether make a shift operation or a reduction.
 - reduce/reduce conflict**: The parser cannot decide which of several reductions to make.
- If a shift-reduce parser cannot be used for a grammar, that grammar is called as non-LR(k) grammar.

The diagram consists of three arrows originating from the text 'non-LR(k) grammar'. The first arrow points to the text 'left to right scanning' with 'lookahead' written below it. The second arrow points to the text 'right-most derivation'. The third arrow points to the letter 'k'.
- left to right scanning
lookahead
- right-most derivation
- k
- An ambiguous grammar can never be a LR grammar.

Shift-Reduce Parsers

- There are two main categories of shift-reduce parsers
- **Operator-Precedence Parser**
 - simple, but only a small class of grammars.
- **LR-Parsers**
 - covers wide range of grammars.
 - **SLR** – simple LR parser
 - **LR** – most general LR parser
 - **LALR** – intermediate LR parser (lookahead LR parser)
 - SLR, LR and LALR work same, only their parsing tables are different.

LR Parsers

- The most powerful shift-reduce parsing (yet efficient) is: LR(k) parsing
- LR parsing is attractive because:
 - LR parsing is most general non-backtracking shift-reduce parsing, yet it is still efficient.
 - The class of grammars that can be parsed using LR methods is a proper superset of the class of grammars that can be parsed with predictive parsers.

LL(1)-Grammars \subset LR(1)-Grammars

- An LR-parser can detect a syntactic error as soon as it is possible to do so a left-to-right scan of the input.

LR Parsers

- **LR-Parsers**
 - covers wide range of grammars.
 - SLR – simple LR parser
 - LR – most general LR parser
 - LALR – intermediate LR parser (look-head LR parser)
 - SLR, LR and LALR work same (they used the same algorithm), only their parsing tables are different.

G:

$S' \rightarrow S$

$S \rightarrow aAcBe$

$A \rightarrow b$

$A \rightarrow Ab$

$B \rightarrow d$

parsing:

abbcde \Leftarrow aAbcde \Leftarrow aAcde \Leftarrow aAcBe \Leftarrow S \Leftarrow S'

G:

$S' \rightarrow S$

$S \rightarrow aAcBe$

$A \rightarrow b$

$A \rightarrow Ab$

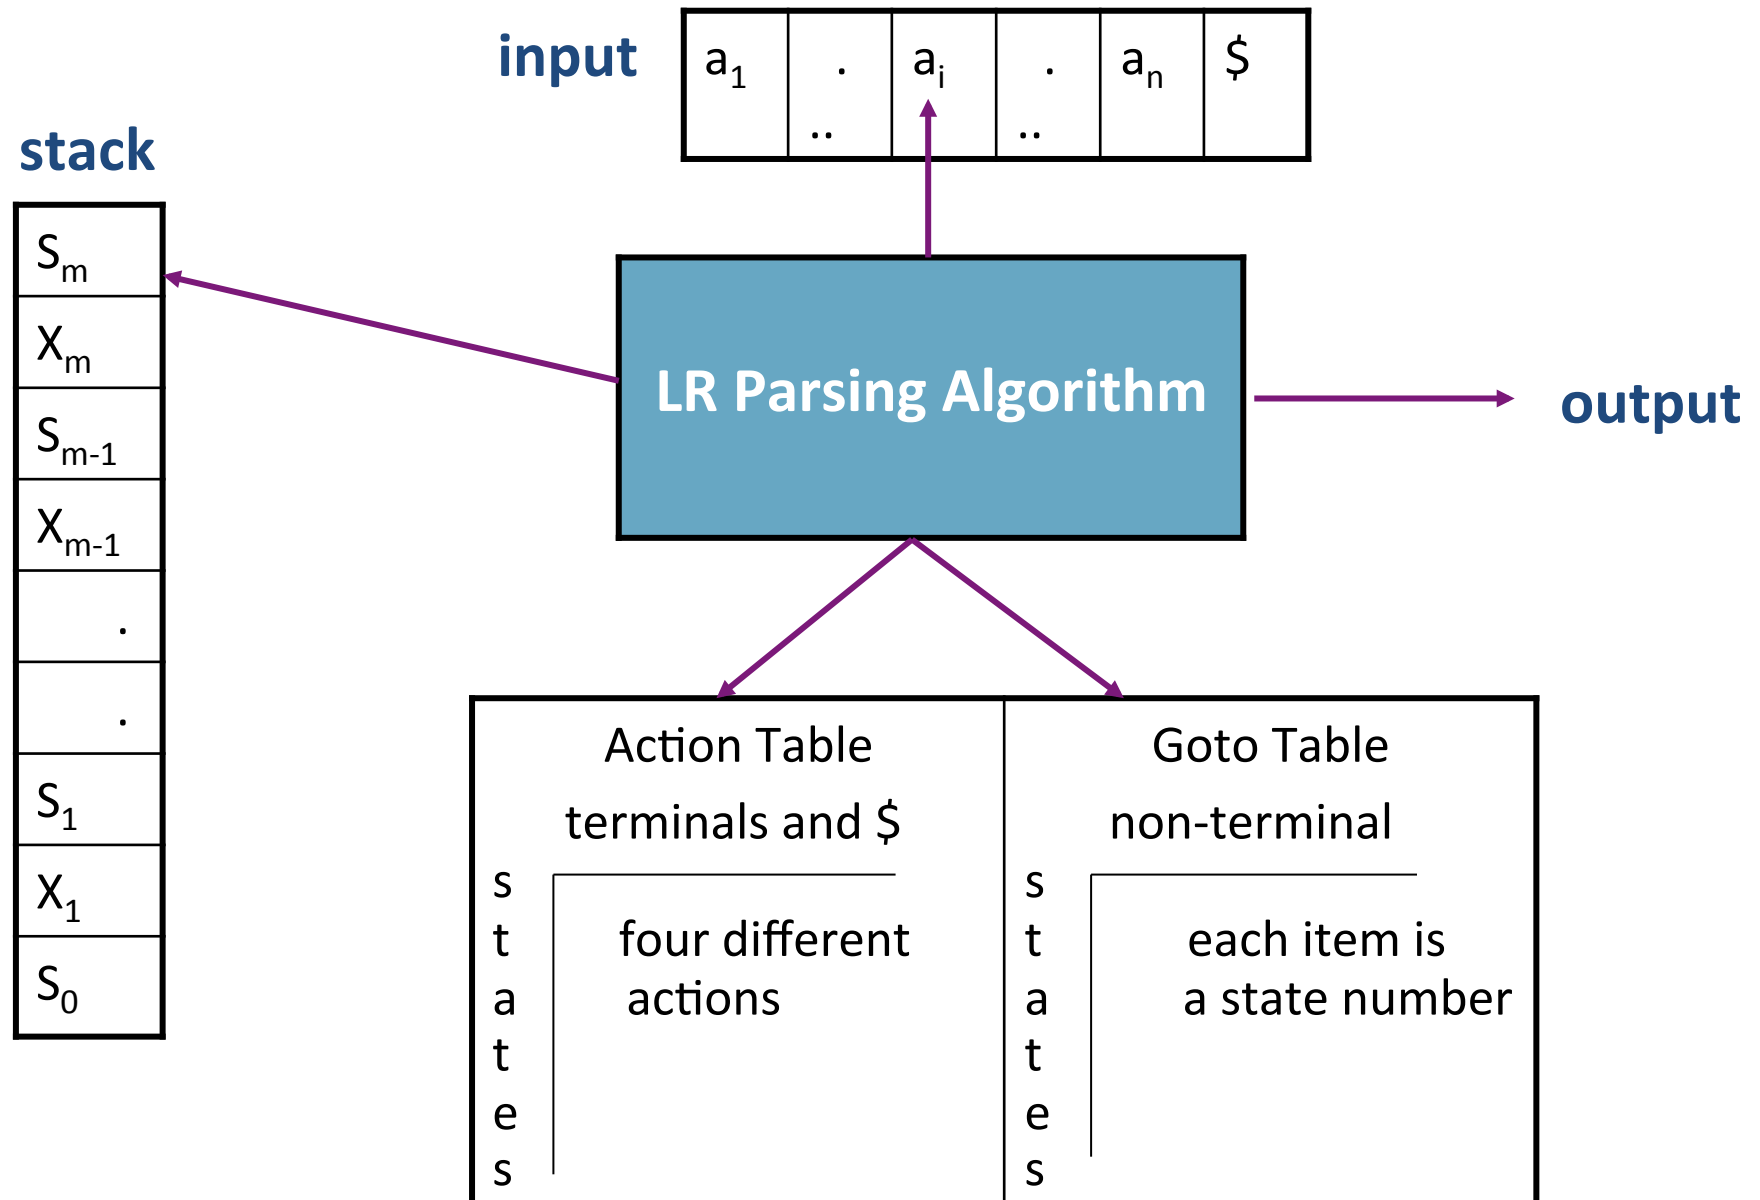

$B \rightarrow d$

steps	stack	input	output
